Q. You are given n strings stored in memory. Then m queries follow. For each query string s , determine whether there exists a stored string t such that t and s differ in exactly one character position. For every query print "Yes" or "No".

Code:

```
#include <bits/stdc++.h>
using namespace std;
int main() {
    int n, m;
    cin >> n >> m;
    vector<string> words(n);
    for (int i = 0; i < n; i++)
        cin >> words[i];
    while (m--) {
        string q;
        cin >> q;
        bool found = false;
```

```
for (string s : words) {
```

```
    if (s.size() != q.size()) continue;
```

```
    int diff = 0;
```

```
    for (int i = 0; i < s.size(); i++) {
```

```
        if (s[i] != q[i]) diff++;
```

```
        if (diff > 1) break;
```

```
    }
```

```
    if (diff == 1) {
```

```
        found = true;
```

```
        break;
```

```
    }
```

```
}
```

```
cout << (found ? "Yes" : "No") << endl;
```

```
}
```

```
return 0;
```

```
}
```
